Category:Workshop participants Category:Vivid (band) members Category:Living people Category:Year of birth missing (living people)Arsenic bioaccumulation, detoxification, and toxicity in European eels (*Anguilla anguilla*): a population-based spatial analysis and ontogenetic interpretation. Arsenic is a global contaminant, present in both the environment and food chains. The impacts of chronic exposure on wildlife

populations are not fully understood. Thus, it is essential to identify the sources of contaminants in different habitats. This study combined quantitative spatial analyses with field observations and laboratory experiments to assess arsenic bioaccumulation and the efficacy of detoxification mechanisms in a high-risk population of European eels (*Anguilla anguilla*) in the Netherlands. Based on this study, the bioaccumulation of arsenic in aquatic organisms is promoted by: (1) fast-growing tissues with high metabolic turnover, e.g., gonads, exocrine pancreas, skin epithelium, and bone marrow, (2) tissues that contribute to respiration in short-lived fish, e.g., skin, gills, and bone marrow, (3) tissues with a low sulfur-containing ligand capacity, e.g., bone, muscle, skin, and gall bladder, and (4) tissues with a low capacity for endocytosis or transcellular arsenic transport, e.g., liver, gills, and kidney. In addition, we present a comprehensive ontogenetic interpretation of how bioconcentration and biouptake of arsenic are established. Arsenic concentrations were highest in liver tissues and lowest in bones. We found no sex-based differences, which was an important inclusion criterion in this study. This suggests that all components of this population were exposed to the same level of arsenic. According to our study, arsenic concentrations in European eels increased from the freshwater habitat to the marine environment. This indicates that both freshwater and marine habitats were contaminated with arsenic. In addition, our results suggest that arsenic bioconcentration in eels is progressive and that it does not exceed the tolerable level of $10 \mu\text{g g}^{-1}$ wet weight. According to our study, the bioconcentration capacity of European eels in the marine environment is similar to that of marine teleosts, and we propose that European eels have the potential to bioconcentrate arsenic for a longer duration than marine teleosts.---
